Data management using Pandas

Data management is a crucial component to statistical analysis and data science work.

This notebook will show you how to import, view, undertand, and manage your data using the Pandas data processing library, i.e., the notebook will demonstrates how to read a dataset into Python, and obtain a basic understanding of its content.

Note that **Python** by itself is a general-purpose programming language and does not provide high-level data processing capabilities. The **Pandas** library was developed to meet this need. **Pandas** is the most popular Python library for data manipulation, and we will use it extensively in this course. **Pandas** provides high-performance, easy-to-use data structures and data analysis tools.

The main data structure that **Pandas** works with is called a **Data Frame**. This is a two-dimensional table of data in which the rows typically represent cases and the columns represent variables (e.g. data used in this tutorial). Pandas also has a one-dimensional data structure called a **Series** that we will encounter when accesing a single column of a Data Frame.

Pandas has a variety of functions named `read_xxx` for reading data in different formats. Right now we will focus on reading `csv` files, which stands for comma-separated values. However the other file formats include `excel`, `json`, and `sql`.

There are many other options to `read_csv` that are very useful. For example, you would use the option `sep='\t'` instead of the default `sep=','` if the fields of your data file are delimited by tabs instead of commas. See here for the full documentation for `read_csv`.

Acknowledgments

- The dataset used in this tutorial is from https://www.coursera.org/ from the course "Understanding and Visualizing Data with Python" by University of Michigan

Importing libraries

```
# Import the packages that we will be using
import numpy as np
import matplotlib.pyplot as plt
import pandas as pd
```

Importing data

```
# Define where you are running the code: colab or local
RunInColab          = True     # (False: no  | True: yes)

# If running in colab:
if RunInColab:
    # Mount your google drive in google colab
    from google.colab import drive
    drive.mount('/content/drive')

    # Find location
    #!pwd
    #!ls
    #!ls "/content/drive/My Drive/Colab Notebooks/MachineLearningWithPython/"

    # Define path del proyecto
    Ruta            = "/content/drive/MyDrive/Colab Notebooks/MachineLearningWithPython/"
```

```
else:
    # Define path del proyecto
    Ruta            = ""
```

```
Drive already mounted at /content/drive; to attempt to forcibly remount, call drive.mount("/content/drive", fo
```

```
# url string that hosts our .csv file
url = Ruta + "cartwheel.csv"
# Read the .csv file and store it as a pandas Data Frame

df = pd.read_csv(url)
```

If we want to print the information about th output object type we would simply type the following: type(df)

```
type(df)
```

```
pandas.core.frame.DataFrame
```

Exploring the content of the data set

Use the `shape` method to determine the numbers of rows and columns in a data frame. This can be used to confirm that we have actually obtained the data the we are expecting.

Based on what we see below, the data set being read here has N_r rows, corresponding to N_r observations, and N_c columns, corresponding to N_c variables in this particular data file.

```
df.shape
```

```
(52, 12)
```

```
Nrows= df.shape[0]
print('Number of rows observations:', str(Nrows))
```

```
Number of rows observations: 52
```

```
Ncolumns= df.shape[1]
print('Number of rows variables:', str(Ncolumns))
```

```
Number of rows variables: 12
```

If we want to show the entire data frame we would simply write the following:

```
df
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGrou
0	1	56.0	F	1	Y	1	62.00	61.0	79	Y	1.
1	2	26.0	F	1	Y	1	62.00	60.0	70	Y	1.
2	3	33.0	F	1	Y	1	66.00	64.0	85	Y	1.

13	14	23.0	F	1	N	0	61.50	57.5	66	Y	1.
14	15	31.0	M	2	Y	1	73.00	74.0	72	Y	1.
15	16	26.0	M	2	Y	1	71.00	72.0	115	Y	1.
16	17	26.0	F	1	N	0	61.50	59.5	90	N	0.
17	18	27.0	M	2	N	0	66.00	66.0	74	Y	1.
18	19	23.0	M	2	Y	1	70.00	69.0	64	Y	1.
19	20	24.0	F	1	Y	1	68.00	66.0	85	Y	1.
20	21	23.0	M	2	Y	1	69.00	67.0	66	N	0.
21	22	29.0	M	2	N	0	71.00	70.0	101	Y	1.
22	23	25.0	M	2	N	0	70.00	68.0	82	Y	1.
23	24	26.0	M	2	N	0	69.00	71.0	63	Y	1.
24	25	23.0	F	1	Y	1	65.00	63.0	67	N	0.
25	26	28.0	M	2	N	0	75.00	76.0	111	Y	1.
26	27	24.0	M	2	N	0	78.40	71.0	92	Y	1.
27	28	25.0	M	2	Y	1	76.00	73.0	107	Y	1.
28	29	32.0	F	1	Y	1	63.00	60.0	75	Y	1.
29	30	38.0	F	1	Y	1	61.50	61.0	78	Y	1.
30	31	27.0	F	1	Y	1	62.00	60.0	72	Y	1.
31	32	33.0	F	1	Y	1	65.30	64.0	91	Y	1.
32	33	38.0	F	1	N	0	64.00	63.0	86	Y	1.
33	34	27.0	M	2	N	0	77.00	75.0	100	Y	1.
34	35	24.0	F	1	N	0	67.80	62.0	98	Y	1.
35	36	27.0	M	2	N	0	68.00	66.0	74	Y	1.
36	37	25.0	F	1	Y	1	65.00	64.5	92	Y	1.
37	38	26.0	F	1	N	0	61.50	59.5	90	Y	1.
38	39	31.0	M	2	Y	1	73.00	74.0	72	Y	1.
39	40	30.0	M	2	Y	1	69.50	66.0	96	Y	1.

39	40	30.0	M	2	Y	1	69.50	66.0	96	Y	1.

As you can see, we have a 2-Dimensional object where each row is an independent observation and each coloum is a variable.

Now, use the the `head()` function to show the first 5 rows of our data frame

42	43	28.0	F	1	Y	1	72.50	72.0	81	Y	1.

```
df.head()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup	S
0	1	56.0	F	1	Y	1	62.0	61.0	79	Y	1.0	
1	2	26.0	F	1	Y	1	62.0	60.0	70	Y	1.0	
2	3	33.0	F	1	Y	1	66.0	64.0	85	Y	1.0	
3	4	39.0	F	1	N	0	64.0	63.0	87	Y	1.0	
4	5	27.0	M	2	N	0	73.0	75.0	72	N	0.0	

Also, you can use the the `tail()` function to show the last 5 rows of our data frame

```
df.tail()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup
47	48	24.0	M	2	N	0	79.5	75.0	82	N	0.0
48	49	28.0	M	2	N	0	77.8	76.0	99	Y	1.0
49	50	30.0	F	1	N	0	74.6	NaN	71	Y	1.0
50	51	NaN	M	2	N	0	71.0	70.0	101	Y	NaN
51	52	27.0	M	2	N	0	NaN	71.5	103	Y	1.0

The columns in a Pandas data frame have names, to see the names, use the `columns` method:

To gather more information regarding the data, we can view the column names with the following function:

```
df.columns
```

```
Index(['ID', 'Age', 'Gender', 'GenderGroup', 'Glasses', 'GlassesGroup',
       'Height', 'Wingspan', 'CWDistance', 'Complete', 'CompleteGroup',
       'Score'],
      dtype='object')
```

Be aware that every variable in a Pandas data frame has a data type. There are many different data types, but most commonly you will encounter floating point values (real numbers), integers, strings (text), and date/time values. When Pandas reads a text/csv file, it guesses the data types based on what it sees in the first few rows of the data file. Usually it selects an appropriate type, but occasionally it does not. To confirm that the data types are consistent with what the variables represent, inspect the `dtypes` attribute of the data frame.

```
df.dtypes
```

```
ID              int64
Age           float64
Gender         object
```

```
GenderGroup        int64
Glasses           object
GlassesGroup       int64
Height           float64
Wingspan         float64
CWDistance         int64
Complete          object
CompleteGroup    float64
Score              int64
dtype: object
```

Summary statistics, which include things like the mean, min, and max of the data, can be useful to get a feel for how large some of the variables are and what variables may be the most important.

```
# Summary statistics for the quantitative variables

df.describe()
```

	ID	Age	GenderGroup	GlassesGroup	Height	Wingspan	CWDistance	CompleteGroup	Score
count	52.000000	51.000000	52.000000	52.000000	51.000000	51.000000	52.000000	51.000000	52.000000
mean	26.500000	28.411765	1.500000	0.500000	68.971569	67.313725	85.576923	0.843137	7.173077
std	15.154757	5.755611	0.504878	0.504878	5.303812	5.624021	14.353173	0.367290	2.211566
min	1.000000	22.000000	1.000000	0.000000	61.500000	57.500000	63.000000	0.000000	2.000000
25%	13.750000	25.000000	1.000000	0.000000	64.500000	63.000000	72.000000	1.000000	6.000000
50%	26.500000	27.000000	1.500000	0.500000	69.000000	66.000000	85.000000	1.000000	8.000000
75%	39.250000	30.000000	2.000000	1.000000	73.000000	72.000000	96.500000	1.000000	9.000000
max	52.000000	56.000000	2.000000	1.000000	79.500000	76.000000	115.000000	1.000000	10.000000

```
# Drop observations with NaN values
df.Age.dropna().describe()

df.Wingspan.dropna().describe()
```

```
count    51.000000
mean     67.313725
std       5.624021
min      57.500000
25%      63.000000
50%      66.000000
75%      72.000000
max      76.000000
Name: Wingspan, dtype: float64
```

It is also possible to get statistics on the entire data frame or a column as follows

- `df.mean()` Returns the mean of all columns
- `df.corr()` Returns the correlation between columns in a data frame
- `df.count()` Returns the number of non-null values in each data frame column
- `df.max()` Returns the highest value in each column
- `df.min()` Returns the lowest value in each column
- `df.median()` Returns the median of each column
- `df.std()` Returns the standard deviation of each column

```
df.median()
```

```
<ipython-input-19-6d467abf240d>:1: FutureWarning: Dropping of nuisance columns in DataFrame reductions (with '
  df.median()
ID               26.5
Age              27.0
GenderGroup       1.5
GlassesGroup      0.5
Height           69.0
Wingspan         66.0
CWDistance       85.0
CompleteGroup     1.0
Score             8.0
dtype: float64
```

How to write a data frame to a File

To save a file with your data simply use the `to_csv` attribute

Examples:

- df.to_csv('myDataFrame.csv')
- df.to_csv('myDataFrame.csv', sep='\t')

```
df.to_csv('myDataFrame.csv')
```

Rename columns

To change the name of a colum use the `rename` attribute

Example:

df = df.rename(columns={"Age": "Edad"})

df.head()

```
df1 = df.rename(columns={"Age":"Edad"})
df1.head()
```

	ID	Edad	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup
0	1	56.0	F	1	Y	1	62.0	61.0	79	Y	1.0
1	2	26.0	F	1	Y	1	62.0	60.0	70	Y	1.0
2	3	33.0	F	1	Y	1	66.0	64.0	85	Y	1.0
3	4	39.0	F	1	N	0	64.0	63.0	87	Y	1.0
4	5	27.0	M	2	N	0	73.0	75.0	72	N	0.0

```
# Back to the original name
```

Selection of colums

As discussed above, a Pandas data frame is a rectangular data table, in which the rows represent observations or samples and the columns represent variables. One common manipulation of a data frame is to extract the data for one case or for one variable. There are several ways to do this, as shown below.

To extract all the values for one column (variable), use one of the following alternatives.

```
a = df.Age
b = df["Age"]
c = df.loc[:, "Age"]
d = df.iloc[:, 1]

#print(a)

df2 = df[["Gender", "GenderGroup"]]
df2.head()
```

	Gender	GenderGroup
0	F	1
1	F	1
2	F	1
3	F	1
4	M	2

Slicing a data set

As discussed above, a Pandas data frame is a rectangular data table, in which the rows represent cases and the columns represent variables. One common manipulation of a data frame is to extract the data for one observation or for one variable. There are several ways to do this, as shown below.

Lets say we would like to splice our data frame and select only specific portions of our data. There are three different ways of doing so.

1. .loc()
2. .iloc()
3. .ix()

We will cover the .loc() and .iloc() splicing functions.

The attibute **.loc()** uses labels/column names, in specific, it takes two single/list/range operator separated by ',', the first one indicates the rows and the second one indicates columns.

```
# Return all observations of CWDistance
df.loc[:,"CWDistance"]

# Return a subset of observations of CWDistance
df.loc[:9, "CWDistance"]

# Select all rows for multiple columns, ["Gender", "GenderGroup"]
df.loc[:,["Gender", "GenderGroup"]]

# Select multiple columns, ["Gender", "GenderGroup"]me
keep = ['Gender', 'GenderGroup']
df_gender = df[keep]

# Select few rows for multiple columns, ["CWDistance", "Height", "Wingspan"]
df.loc[4:9, ["CWDistance", "Height", "Wingspan"]]

# Select range of rows for all columns
```

```
df.loc[10:15,:]
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup
10	11	30.0	M	2	Y	1	69.50	66.0	96	Y	1.0
11	12	28.0	F	1	Y	1	62.75	58.0	79	Y	1.0
12	13	25.0	F	1	Y	1	65.00	64.5	92	Y	1.0
13	14	23.0	F	1	N	0	61.50	57.5	66	Y	1.0
14	15	31.0	M	2	Y	1	73.00	74.0	72	Y	1.0
15	16	26.0	M	2	Y	1	71.00	72.0	115	Y	1.0

The attribute **iloc()** is an integer based slicing.

```
# Todas las filas de las primeras 4 variables.
#df.iloc[:, :4]

# Todas las columnas las primeras 4 observaciones.
#df.iloc[:4, :]

# Todas las observaciones de las variables de la 4 a la 7, son 4 variables.
#df.iloc[:, 3:7]

# Selecciona las observaciones de la lectura de la 4 a la 7 y las variables 2 y 3, ya que no incluye ell limite sup
#df.iloc[4:8, 2:4]

# This is incorrect:
#df.iloc[1:5, ["Gender", "GenderGroup"]]
```

Get unique existing values

List unique values in the one of the columns

df.Gender.unique()

```
# List unique values in the df['Gender'] column
df.Gender.unique()
```

```
array(['F', 'M'], dtype=object)
```

```
# Lets explore df["GenderGroup] as well
df.GenderGroup.unique()
```

```
array([1, 2])
```

Filter, Sort and Groupby

With **Filter** you can use different conditions to filter columns. For example, df[df[year] > 1984] would give you only the column year is greater than 1984. You can use & (and) or | (or) to add different conditions to your filtering. This is also called boolean

filtering.

df[df["Height"] >= 70]

With **Sort** is possible to sort values in a certain column in an ascending order using `df.sort_values("ColumnName")` or in descending order using `df.sort_values(ColumnName, ascending=False)`.

Furthermore, it's possible to sort values by Column1Name in ascending order then Column2Name in descending order by using `df.sort_values([Column1Name,Column2Name],ascending=[True,False])`

df.sort_values("Height")

df.sort_values("Height",ascending=False)

The attribute **Groupby** involves splitting the data into groups based on some criteria, applying a function to each group independently and combining the results into a data structure. df.groupby(col) returns a groupby object for values from one column while df.groupby([col1,col2]) returns a groupby object for values from multiple columns.

df.groupby(['Gender'])

```
df.groupby(['Gender'])
```

```
<pandas.core.groupby.generic.DataFrameGroupBy object at 0x7fb3e78d3cd0>
```

Size of each group

df.groupby(['Gender']).size()

df.groupby(['Gender','GenderGroup']).size()

```
df.groupby(['Gender']).size()
```

```
Gender
F    26
M    26
dtype: int64
```

This output indicates that we have two types of combinations.

- Case 1: Gender = F & Gender Group = 1
- Case 2: Gender = M & GenderGroup = 2.

This validates our initial assumption that these two fields essentially portray the same information.

Data Cleaning: handle with missing data

Before getting started to work with your data, it's a good practice to observe it thoroughly to identify missing values and handle them accordingly.

When reading a dataset using Pandas, there is a set of values including 'NA', 'NULL', and 'NaN' that are taken by default to represent a missing value. The full list of default missing value codes is in the '`read_csv`' documentation here. This document

also explains how to change the way that '`read_csv`' decides whether a variable's value is missing.

Pandas has functions called `isnull` and `notnull` that can be used to identify where the missing and non-missing values are located in a data frame.

Below we use these functions to count the number of missing and non-missing values in each variable of the datasetr.

```
df.isnull()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGro
0	False	False	False	False	False	False	False	False	False	False	Fal
1	False	False	False	False	False	False	False	False	False	False	Fal
2	False	False	False	False	False	False	False	False	False	False	Fal
3	False	False	False	False	False	False	False	False	False	False	Fal
4	False	False	False	False	False	False	False	False	False	False	Fal
5	False	False	False	False	False	False	False	False	False	False	Fal
6	False	False	False	False	False	False	False	False	False	False	Fal
7	False	False	False	False	False	False	False	False	False	False	Fal
8	False	False	False	False	False	False	False	False	False	False	Fal
9	False	False	False	False	False	False	False	False	False	False	Fal
10	False	False	False	False	False	False	False	False	False	False	Fal
11	False	False	False	False	False	False	False	False	False	False	Fal
12	False	False	False	False	False	False	False	False	False	False	Fal
13	False	False	False	False	False	False	False	False	False	False	Fal
14	False	False	False	False	False	False	False	False	False	False	Fal
15	False	False	False	False	False	False	False	False	False	False	Fal
16	False	False	False	False	False	False	False	False	False	False	Fal
17	False	False	False	False	False	False	False	False	False	False	Fal
18	False	False	False	False	False	False	False	False	False	False	Fal
19	False	False	False	False	False	False	False	False	False	False	Fal
20	False	False	False	False	False	False	False	False	False	False	Fal

Unfortunately, our output indicates that some of our columns contain missing values so we are no able to continue on doing analysis with those colums

```
df.notnull()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGrou
0	True	True	True	True	True	True	True	True	True	True	Tru
1	True	True	True	True	True	True	True	True	True	True	Tru
2	True	True	True	True	True	True	True	True	True	True	Tru
3	True	True	True	True	True	True	True	True	True	True	Tru
4	True	True	True	True	True	True	True	True	True	True	Tru

```

Now we use these functions to count the number of missing and non-missing values in a single variable in the dataset

print(df.Height.notnull().sum())

print(pd.isnull(df.Height).sum())

```
# Extract all non-missing values of one of the columns into a new variable
x = df.Age.dropna().describe()
x.describe()
```

```
count     8.000000
mean     30.645922
std      16.044470
min       5.755611
25%      24.250000
50%      27.705882
75%      35.250000
max      56.000000
Name: Age, dtype: float64
```

Add and eliminate columns

In some cases it is useful to create or eiminate new columns

```
df.head()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup	S
0	1	56.0	F	1	Y	1	62.0	61.0	79	Y	1.0	
1	2	26.0	F	1	Y	1	62.0	60.0	70	Y	1.0	
2	3	33.0	F	1	Y	1	66.0	64.0	85	Y	1.0	
3	4	39.0	F	1	N	0	64.0	63.0	87	Y	1.0	
4	5	27.0	M	2	N	0	73.0	75.0	72	N	0.0	

```
# Add a new column with new data

# Create a column data
NewColumnData = df.Wingspan/df.CWDistance

# Insert that column in the data frame
df.insert(12, "Wingspan/CWDDistance", NewColumnData, True)

df.head()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup	S
0	1	56.0	F	1	Y	1	62.0	61.0	79	Y	1.0	
1	2	26.0	F	1	Y	1	62.0	60.0	70	Y	1.0	
2	3	33.0	F	1	Y	1	66.0	64.0	85	Y	1.0	
3	4	39.0	F	1	N	0	64.0	63.0	87	Y	1.0	
4	5	27.0	M	2	N	0	73.0	75.0	72	N	0.0	

```
# # Eliminate inserted column
#df.drop("ColumnInserted", axis=1, inplace = True)
# #df.drop(columns=['ColumnInserted'], inplace = True)
# # Remove three columns as index base
# #df.drop(df.columns[[12]], axis = 1, inplace = True)
#
df.head()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup	S
0	1	56.0	F	1	Y	1	62.0	61.0	79	Y	1.0	
1	2	26.0	F	1	Y	1	62.0	60.0	70	Y	1.0	
2	3	33.0	F	1	Y	1	66.0	64.0	85	Y	1.0	
3	4	39.0	F	1	N	0	64.0	63.0	87	Y	1.0	
4	5	27.0	M	2	N	0	73.0	75.0	72	N	0.0	

```
# # Add new column derived from existing columns
#
# # The new column is a function of another column
df["AgeInMonths"] = df["Age"] * 12
#
df.head()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup	S
0	1	56.0	F	1	Y	1	62.0	61.0	79	Y	1.0	
1	2	26.0	F	1	Y	1	62.0	60.0	70	Y	1.0	
2	3	33.0	F	1	Y	1	66.0	64.0	85	Y	1.0	
3	4	39.0	F	1	N	0	64.0	63.0	87	Y	1.0	
4	5	27.0	M	2	N	0	73.0	75.0	72	N	0.0	

```
# # Eliminate inserted column
# df.drop("AgeInMonths", axis=1, inplace = True)
#
# df.head()

# Add a new column with text labels reflecting the code's meaning

df["GenderGroupNew"] = df.GenderGroup.replace({1: "Female", 2: "Male"})

# Show the first 5 rows of the created data frame

## Eliminate inserted column
# df.drop("GenderGroupNew", axis=1, inplace = True)
##df.drop(['GenderGroupNew'],vaxis='columns',vinplace=True)

## Add a new column with strata based on these cut points
#
## Create a column data
#NewColumnData = df.Age/df.Age
#
## Insert that column in the data frame
#df.insert(1, "ColumnStrata", NewColumnData, True)
#
#df["ColumnStrata"] = pd.cut(df.Height, [60., 63., 66., 69., 72., 75., 78.])
#
## Show the first 5 rows of the created data frame
#df.head()

## Eliminate inserted column
#df.drop("ColumnStrata", axis=1, inplace = True)
#
#df.head()

# Drop several "unused" columns
#vars = ["ID", "GenderGroup", "GlassesGroup", "CompleteGroup"]
#df.drop(vars, axis=1, inplace = True)
```

Add and eliminate rows

In some cases it is requiered to add new observations (rows) to the data set

```
# Print tail
df.tail()
```

	ID	Age	Gender	GenderGroup	Glasses	GlassesGroup	Height	Wingspan	CWDistance	Complete	CompleteGroup
47	48	24.0	M	2	N	0	79.5	75.0	82	N	0.0
48	49	28.0	M	2	N	0	77.8	76.0	99	Y	1.0
49	50	30.0	F	1	N	0	74.6	NaN	71	Y	1.0
50	51	NaN	M	2	N	0	71.0	70.0	101	Y	NaN
51	52	27.0	M	2	N	0	NaN	71.5	103	Y	1.0

df.loc[len(df.index)] = [26, 24, 'F', 1, 'Y', 1, 66, 'NaN', 68, 'N', 0, 3] df.tail()

```
## Eliminate inserted row
#df.drop([28], inplace = True )
#
#df.tail()
```

Cleaning your data: drop out unused columns and/or drop out rows with any missing values

```
# Drop unused columns
#vars = ["ID", "GenderGroup", "GlassesGroup", "CompleteGroup"]
#df.drop(vars, axis=1, inplace = True)

#vars = ["Age", "Gender", "Glasses", "Height", "Wingspan", "CWDistance", "Complete", "Score"]
#df = df[vars]

# Drop rows with any missing values
#df = df.dropna()

# Drop unused columns and drop rows with any missing values
vars = ["Age", "Gender", "Glasses", "Height", "Wingspan", "CWDistance", "Complete", "Score"]
df = df[vars].dropna()

df
```
